Species Profiles: Life Histories and Environmental Requirements of Coastal Fishes and Invertebrates (Gulf of Mexico)

COMMON RANGIA

Fish and Wildlife Service

Coastal Ecology Group Waterways Experiment Station

U.S. Department of the Interior

U.S. Army Corps of Engineers

This is one of the first reports to be published in the new "Biological Report" series. This technical report series, published by the Research and Development branch of the U.S. Fish and Wildlife Service, replaces the "FWS/OBS" series published from 1976 to September 1984. The Biological Report series is designed for the rapid publication of reports with an application orientation, and it continues the focus of the FWS/OBS series on resource management issues and fish and wildlife needs.

Species Profiles: Life Histories and Environmental Requirements of Coastal Fisheries and Invertebrates (Gulf of Mexico)

COMMON RANGIA

This profile should be cited as follows:

LaSalle, M.W., and A.A. de la Cruz. 1985. Species profiles: life histories and environmental requirements of coastal fishes and invertebrates (Gulf of Mexico) -- common rangia. U.S. Fish Wildl. Serv. Biol. Rep. 82(11.31). U.S. Army Corps of Engineers, TR EL-82-4. 16 pp.

PREFACE

This species profile is one of a series on coastal aquatic organisms, principally fish, of sport, commercial, or ecological importance. The profiles are designed to provide coastal managers, engineers, and biologists with a brief comprehensive sketch of the biological characteristics and environmental requirements of the species and to describe how populations of the species may be expected to react to environmental changes caused by coastal development. Each profile has sections on taxonomy, life history, ecological role, environmental requirements, and economic importance, if applicable. A three-ring binder is used for this series so that new profiles can be added as they are prepared. This project is jointly planned and financed by the U.S. Army Corps of Engineers and the U.S. Fish and Wildlife Service.

Suggestions or questions regarding this report should be directed to one of the following addresses.

ACKNOWLEDGMENTS

We thank Dr. Courtney T. Hackney, University of North Carolina at Wilmington and Dr. H. Dickson Hoese, University of Southwestern Louisiana, for their critical reviews of the manuscript; T. Dale Bishop and Darryl R. Clark for information and help with the literature search; Mark F. Godcharles, Jake M. Valentine, and personnel of the Alabama State Docks Department and the U.S. Army Corps of Engineers, Mobile District, for providing comments and unpublished reports; Jeanne J. Hartley for her illustration of rangia; and Dr. Robert J. Muncy, Betty Muncy, and Cindy Mills for help in the preparation of the manuscript.

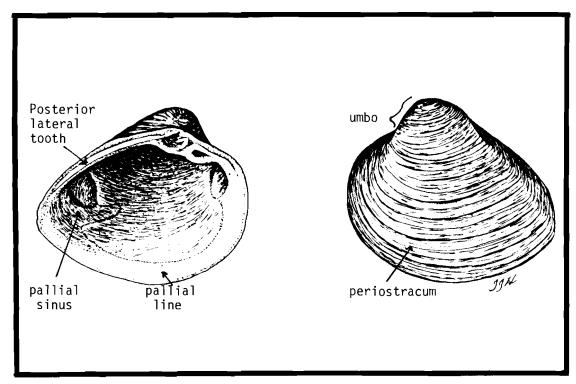

Figure 1. Common rangia.

COMMON RANGIA

NOMENCLATURE/TAXONOMY/RANGE

Scientific name
cuneata (Gray) (Figure 1)
Preferred common nameCommon
rangia (Andrews 1971; Fotheringham
and Brunenmeister 1975)
Other common namesBrackish
water clam, Louisiana road clam
ClassMollusca
OrderEulamellibranchia
FamilyMactridae

Geographic range: The common rangia is found along the Gulf of Mexico coast (Figure 2) from northwest Florida to Laguna de Terminos, Campeche, Mexico (Dall 1894; Andrews 1971; Ruiz 1975), and along the Atlantic coast as far north as Maryland (Pfitzenmeyer and Drobeck 1964; Gallagher and Wells 1969; Hopkins and Andrews 1970) and

New Jersey (Woodburn 1962). Before 1956, living common rangia had not been collected along the Atlantic coast (Wells 1961) probably because earlier sampling in brackish water areas had been inadequate. Common rangia inhabit low salinity (0 to 18 ppt) estuarine habitats (Parker 1966; Christmas 1973; Hopkins et al. 1973; Swingle and Bland 1974).

Geologically, the common rangia has been found in Pliocene deposits in the Carolinas and Florida and in Pleistocene deposits in Chesapeake Bay and the Potomac River, the Carolinas, Florida, the entire north coast of the Gulf of Mexico (Figure 2), and the north coast of South America (Conrad 1840; Dall 1894; Maury 1920; Richards 1939).

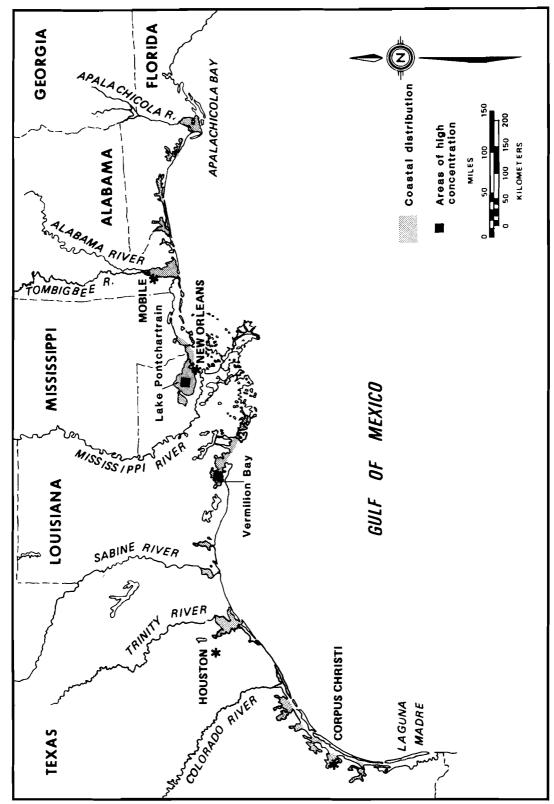

Figure 2. Distribution of common rangia along the northern coast of the Gulf of Mexico.

MORPHOLOGY/IDENTIFICATION AIDS

The following description of common rangia is taken from Abbott (1954)and Andrews (1971, 1981). Adults range from 2.5 to 6.0 cm in The valves are obliquely lenath. ovate, thick, and heavy (Figure 1). The exterior of the shell is covered strong, rather periostracum that ranges from light brown to grayish brown to black. The umbones are prominent and are near the anterior end. The shell interior is glossy white with a blue-gray tinge. small pallial sinus is but distinct. The posterior lateral tooth is long (Figure 1). Dall (1894) mentions that most of the variability in form is related to the differences in the height of the umbones and the shape of the posterior margin of the Rangia cuneata var. nasutus 1894) is believed to be a (Dall rostrate form of R. rostrate form of \underline{R} . cuneata (Abbott 1954) and may be confused with a closely related species, the brown rangia (Rangia flexuosa [Conrad]). The brown rangia is 2.5 to 4.0 cm long resembles an elongate common rangia; however, brown rangia can be easily separated from common rangia by the short posterior lateral tooth and the nondistinct pallial sinus. Brown rangia is found from Louisiana to Texas and Vera Cruz, Mexico (Andrews 1971). but is much less common than the common rangia.

REASONS FOR INCLUSION IN SERIES

The common rangia is an important estuarine component of ecosystems (Parker 1959; Odum 1967; Odum and Copeland 1969; Copeland et al. 1974) accounting, for example, for nearly 95% of the benthic biomass in the James River Estuary, Virginia (Cain 1975). In low salinity estuarine areas common rangia functions as a link between primary producers and secondary consumers. As a non-selective filter feeder. rangia transforms large quantities of plant detritus and phytoplankton into clam biomass (Darnell 1958; Olsen 1972,

1973, 1976a; Hoese 1973). In turn, this biomass is consumed by fishes, crustaceans, and ducks (Suttkus et al. 1954; Darnell 1958; Gunter and Shell 1958; Harmon 1962; North Carolina Bureau of Sport Fisheries and Wildlife 1965; O'Heeron 1966; Cain 1972; Tarver and Dugas 1973). The shells provide hard substrate for epifaunal attachment (Hoese 1973).

The common rangia was a food item of prehistoric Indians (McIntire 1958) and it is still occasionally canned and in New Jersey, Texas, Carolina, and Mexico (Singley 1893: Woodburn 1962; Wass and Haven 1970; Department of Commerce 1971). Economically, common rangia is more important as a source of shells for road building and in the manufacture of many industrial products (Tarver and Dugas 1973; Swingle and Bland 1974; Arndt 1976). Much of this material is dredged from buried deposits in estuaries.

LIFE HISTORY

Spawning

The reproductive cvcle and environmental conditions necessary for spawning are well known for common The reproductive cycle was in Louisiana by Fairbanks ranqia. studied (1963), in Virginia by Cain (1975), in Florida by Olsen (1976b), and in Campeche. Mexico by Rogers Garcia-Cubas (1981).Most rangia spawned from March to May and from late summer to November in Louisiana and from February to June and September to November in Mexico. In both areas. spawning may be continuous.

In Virginia, gametogenesis began in early April and continued throughout the summer; gametes were ripe from May through November. Gametogenesis was initiated when water temperature rose to 15°C, spawning and initiated by a rapid increase or decrease in salinity (Cain 1975). upstream areas of the James River.

Virginia, clams required a salinity increase of about 5 ppt associated with reduced freshwater output, but in downstream areas they required a salinity decrease of about 10 to 15 ppt associated with increased freshwater output. Spawning peaked at 5 ppt in fall. In Florida, ripe gametes and spawning were reported from July through November; spawning peaked in September. Temperature and salinity increases were suspected of triggering spawning (Olsen 1976b).

In spawning, common rangia release gametes directly into the water. ratios were reported to be near 1:1 in Louisiana (Fairbanks 1963) and Mexico (Rogers and Garcia-Cubas 1981), but females outnumbered males in Virginia The incidence of herma-(Cain 1972). phroditism in this clam was reported to be 0.1% in Mexico (Rogers and Garcia-Cubas 1981) and 2.1% in Florida (Olsen The minimum length of mature 1976b). Pontchartrain, adults in Lake Louisiana, was 24 mm (Fairbanks 1963). From data on annual growth increments, Fairbanks (1963) inferred that a clam could reach minimum length in 2 to 3 In the James River, Virginia, Cain (1972) reported that gonads were mature in clams as small as 14 mm, which were probably clams in their second year of life.

No fecundity data are available on common rangia.

Larvae and Postlarvae

The early stages of development of common rangia were studied in Louisiana by Fairbanks (1963) and in Virginia by Chanley (1965). Fairbanks reported that the average diameter of eggs was 69 μM. Ciliated blastula 8.5 developed (h) hours after fertilization, a pelagic trochophore at 26.3 h, and a veliger at 34.3 h (93 μ m me an diameter). Ιn Virginia, Chanley reported that shelled larvae appeared within 24 h after fertiliza-The length of different life tion. stages were follows: as

straight-hinged larvae 0.75 to 130 $\mu m;$ unbowed larvae 120 to 175 $\mu m;$ and pediveligers (metamorphosed) 160 to 175 $\mu m.$ Pediveligers began to settle, lose the velum, and attain gills at 175 to 180 $\mu m.$ Metamorphosis began after 7 days (Chanley 1965).

Most settling of larvae in the James River, Virginia, took place between September and March when the animals were 230 to 500 μm long and averaged 300 μm (Cain 1975). A second settling period occurred in midsummer. In Lake Pontchartrain, Louisiana, Fairbanks (1963) collected juveniles as small as 375 μm while Hoese (1973) observed several small clams (< 1 mm long) attached to a hydroid colony.

How the juvenile rangia disperse is uncertain. They may be transported to upstream areas in the more saline bottom water in an incoming tide, or by swimming during low flow or both (Cain 1975). Fairbanks (1963) reported that larvae were capable of selecting substrate for setting and preferred substrates high in organic content.

Adult Activity and Feeding

Common rangia move little after settling. Fairbanks (1963) observed little movement of clams in aquaria. Sikora et al. (1981) suggested that rangia are capable only of vertical movement in the sediment. Olsen (1973) reported that clams did not move in aquaria over a 4-month period even when given a choice of substrates.

Feeding of common rangia is controlled by gill palp articulations and ciliary currents over the gills (Olsen 1972). The animal extrudes pseudofeces from the mantle cavity, through the inhalant siphon when the valves are quickly closed.

Life Span

The life span of the common rangia has not been confirmed. If one relates the mean length (about 40 mm) of rangia

collected in Louisiana (Table 1), to estimates of growth rate (Fairbanks 1963; Wolfe and Petteway 1968), the average life span is about 4 to 5 years. A clam of the maximum expected length of 75 mm, reported by Wolfe and Petteway (1968) in Chesapeake Bay, would be 10 years old. Hopkins et al. (1973) estimated a maximum life span of 15 years.

GROWTH CHARACTERISTICS

Growth Rate

Annual growth increments of common rangia in the Gulf of Mexico are reported to vary from 0 to 20 mm (Fairbanks 1963; Gooch 1971; Tarver and Dugas 1973). Annual growth increments, estimated for the first 3 years of life for two populations in Lake Pontchartrain, Louisiana, were 15 to 20

mm. 5 to 9 mm, and 4 to 5 mm, respectively (Fairbanks 1963). From mean height data for clams collected in Lake Pontchartrain, Tarver and Dugas (1973) reported as much as 7.2 mm growth in a 2-month period. This rapid growth appeared to be related to warm temperatures. Annual growth rates have been reported to range from 0 to 9.7 mm for Vermilion Bay, Louisiana (Gooch 1971) and to be 3 mm in Trinity Bay, Texas (Bedinger 1974). Wolfe and (1968)the Petteway calculated following von Bertalanffy growth curve for a common rangia population in the Trent River, North Carolina: L = 75.62 (1-0.995 $e^{-0.0193t}$). The largest predicted length of 75.6 mm represent 10 years of growth.

Size

Maximum length reported was 94 mm for a common rangia from Grand Gosier Island, Louisiana (H.D. Hoese, Univ.

Table 1. Range of lengths (mm) or heights (mm) of common rangia examined in four areas of Louisiana.

Area	Length	Height	References

Southwestern La.; pers. comm.). Mean sizes (length, anterior to posterior; height. umbo to ventral margin) reported from other Louisiana estuaries are shown in Table 1. Parker (1960) and Hoese (1973) reported that the largest clams were found in the lower salinity areas of estuaries, whereas, Tarver and Dugas (1973) found that clam size increased with salinity. Virginia, Cain (1972) noted that clams living in sand were typically larger than those living in mud.

THE FISHERY

The foremost commercial value of common rangia is in the use of fossil for road building material, oyster cultch, and as a source of calcium carbonate for the manufacture of glass, chemicals, chicken and cattle feed, wallboard, and agricultural lime (Tarver and Dugas 1973; Swingle and Bland 1974; Arndt 1976). Clam shells harvested Ьy large commercial hydraulic dredges. By far the largest living concentrations of clams along the Louisiana coast. The minimum standing crop of clams estimated to be between the Atchafalaya River and Sabine Lake, Louisiana, was between 24 billion and 48 billion clams (Hoese 1973). Because of the relatively slow growth rate of rangia, Hoese (1973) suggested that no more than 5% of the population should livina clam annually if current harvested production of fossil shells is to be maintained; however, at an annual recruitment of 5% (Fairbanks 1963) the shell deposits estimated in Pontchartrain would be nearly exhausted in 35 years; at 3% Tarver and Dugas (1973) estimated depletion in 18 years.

The potential sources of common rangia shell along the gulf coast have been listed by Arndt (1976). In Texas, shell occurs in the upper reaches of San Antonio Bay, Nueces and Lavaca Bays, Galveston Bay, Trinity Bay, and Sabine Lake. In Louisiana, deposits

extend from Point au Fer (Atchafalaya the Texas west to border. Calcasieu and Sabine Lakes, and Lake Pontchartrain. In Mississippi, clams live in the Pearl River Estuary and Mississippi Sound; in Alabama, in upper Bay: and in Florida Choctawhatchee Bay, Tampa Bay. Caloosahatchie River (Arndt 1976), and the upper reaches of Charlotte Harbor (Woodburn 1962).

Louisiana Wildlife The and Fisheries Commission (1968) estimated a statewide production of about 5 million cubic yards of clam shell in 1968 compared with 300,000 cubic yards annually in the mid-1930's. maximum annual harvest of shell in the qulf States was 21.2 million tons in 1967 compared with 468,000 tons in 1912 (Arndt 1976). Of the material dredged in 1967, an estimated 12.2 million tons used in construction remainder for road base, asphalt fill, poultry grit, cattle roughage, filter material, and whiting (pigment).

Native Americans used common rangia as food, as evidenced from shell deposits in Indian middens along the gulf coast (Singley 1893; McIntire 1958). The canning of rangia in Texas under the name of "little neck clams" the Givens Oyster Company was reported by Singley (1893). Rangia were also canned at Cape May, New Jersey (Woodburn 1962) and in North Carolina (U.S. Department of Commerce 1971). Rangia have been collected and consumed from the Potomac Creek of the Potomac River, Maryland (Pfitzenmeyer and Drobeck 1964), to Mexico where Wass and Haven (1970) reported that this clam was served with rice as "Paella a valencianna" in restaurants. potential use of this clam as food, however, is severely limited bν contamination of large potential sources by pollution (Christmas 1973; Swingle and Bland 1974). Rangia are also used as bait for blue crabs (Godcharles and Jaap 1973).

Trophic Level

Common rangia serve link to secondary producers and consumers in estuarine areas. Rangia non-selective filter feeders (Darnell 1958; Olsen 1976a) ingesting quantities of detritus and phytoplankton. Darnell (1958) reported that qut contents contained 70% unidentifiable detritus, 10% sand, 17% (possibly Anabaena algae or Microcystis) as well as traces of diatoms, foraminifera, and vascular plant material. Olsen (1976a) reported phytoplankton of species stomach contents of common rangia, a large portion although of the material ingested was detritus (46 to 81%, depending on tidal conditions).

Predators and Parasites

Common rangia are preyed upon by fish, crustaceans, mollusks, and ducks (Table 2; Suttkus et al. 1954; Darnell 1958: Gunter and Shell 1958: Harmon 1962; North Carolina Bureau of Sport Fisheries and Wildlife 1965; O'Heeron Cain 1972; Tarver and 1973). In addition, moon shell snails (Polinices spp.) may be predators as suggested by drill holes in rangia shells (Hoese 1973). Common rangia are abundant in the diets of blue catfish, freshwater drum, spot, black drum, river shrimp, and blue crab in Lake Pontchartrain, Louisiana (Darnell 1958, 1961). The smaller rangia are subjected to the greatest predation Clams as large as 40 mm pressure. (length or height), however, are eaten by fishes such as sheepshead and black drum (Darnell 1958; Tarver and Dugas 1973). A potential group of predators not mentioned by the above authors are ctenophores (i.e., <u>Mnemioposis</u>) which sometime appear in tremendous numbers at certain times of the year (M.W. LaSalle, pers. observ.). Ctenophores can cause mass mortality of larvae if coincidental with rangia spawning.

The common rangia is parasitized by larvae of fellodistomatid trematodes (Fairbanks 1963). Cercariae sporocysts of this parasite are found in the gonadal tissue, giving it an orange coloration and effecting castration. large 0n1y clams infected.

Competitors

Potential competitors of common rangia may be reduced by the wide range of salinities tolerated by this (Odum 1967). Pol vmesoda caroliniana has feeding habits identical to those of rangia (Olsen 1973, 1976a), but is spatially separated from rangia; it is found primarily in intertidal areas or in small numbers in the shallow nearshore subtidal areas. In contrast, rangia live largely in the subtidal zone. Other potential competitors apparently not adapted to fluctuating salinities.

Spatial Distribution

Common rangia primarily are restricted to low salinity (< 19 ppt) estuaries (Maury 1920; Pulley 1952; Parker 1955, 1956, 1960; Moore 1961; Parker 1966; Odum 1967; Christmas 1973; Hoese 1973; Hopkins 1970; Hopkins et 1973; Swingle and Bland 1974). Rangia have been reported from areas as far as 25 miles upstream in delta rivers (Swingle and Bland 1974), but most prefer salinities of 5 to 15 ppt. Tarver and Dugas (1973) found that concentrations of clams were highest adjacent to a potential source of fresh or salt water, which may be related to the need for salinity shock required for spawning (Cain 1973). Concentrations of clams were greatest periphery of around the Pontchartrain and Lake Maurepas (Tarver 1972; Dugas et al. 1974). Dispersion of adult clams is commonly clumped

Table 2. Reported predators of adult and juvenile common rangia.

whereas juveniles may be distributed more uniformly (Fairbanks 1963).

Density

The density of clams varies greatly (for reasons discussed later). The highest density of adult clams was

 $818/m^2$ in Lake Maurepas, Louisiana (Tarver and Dugas 1973), and $238/m^2$ in Vermilion Bay, Louisiana. Average density of clams from shallow water areas between the Atchafalaya River and Sabine Lake was $11.1/m^2$ for adults, $14/m^2$ for juvenile clams > 10 mm, and $28/m^2$ for juvenile clams < 10 mm (Hoese 1973). Densities as high as

DEPARTMENT OF THE INTERIORU.S. FISH AND WILDLIFE SERVICE

As the Nation's principal conservation agency, the Department of the Interior has responsibility for most of our nationally owned public lands and natural resources. This includes fostering the wisest use of our land and water resources, protecting our fish and wildlife, preserving the environmental and cultural values of our national parks and historical places, and providing for the enjoyment of life through outdoor recreation. The Department assesses our energy and mineral resources and works to assure that their development is in the best interests of all our people. The Department also has a major responsibility for American Indian reservation communities and for people who live in island territories under U.S. administration.
